

Network Programming:

Sockets and anatomy of a connection

Sockets Interface

- Set of system-level functions used in conjunction with Unix I/O to build network applications.
- Created in the early 80's as part of the original Berkeley distribution of Unix that contained an early version of the Internet protocols.
- Available on all modern systems
 - Unix variants, Windows, OS X, IOS, Android, ARM

Sockets

■ What is a socket?

- To the kernel, a socket is an endpoint of communication
- To an application, a socket is a file descriptor that lets the application read/write from/to the network
 - **Remember:** All Unix I/O devices, including networks, are modeled as files

■ Clients and servers communicate with each other by reading from and writing to socket descriptors

■ The main distinction between regular file I/O and socket I/O is how the application “opens” the socket descriptors

Socket Address Structures

■ Generic socket address:

- For address arguments to **connect**, **bind**, and **accept**
- Necessary only because C did not have generic (**void ***) pointers when the sockets interface was designed
- For casting convenience, Stevens convention (*Unix Network Programming*):
typedef struct sockaddr SA;

```
struct sockaddr {  
    uint16_t    sa_family;    /* Protocol family */  
    char        sa_data[14]; /* Address data. */  
};
```

sa_family

sa_data

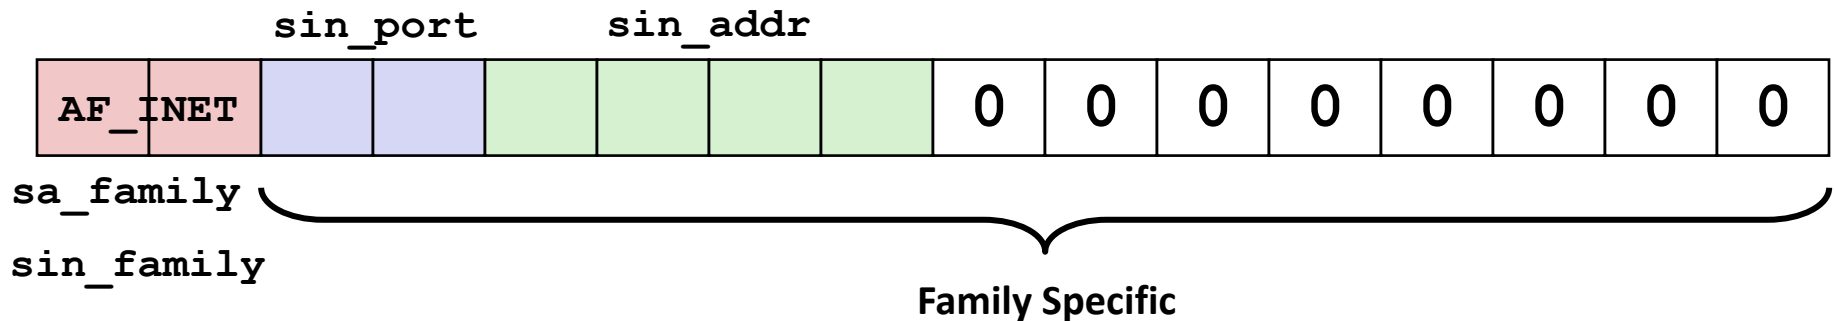

Family Specific

Socket Address Structures

■ Internet-specific socket address:

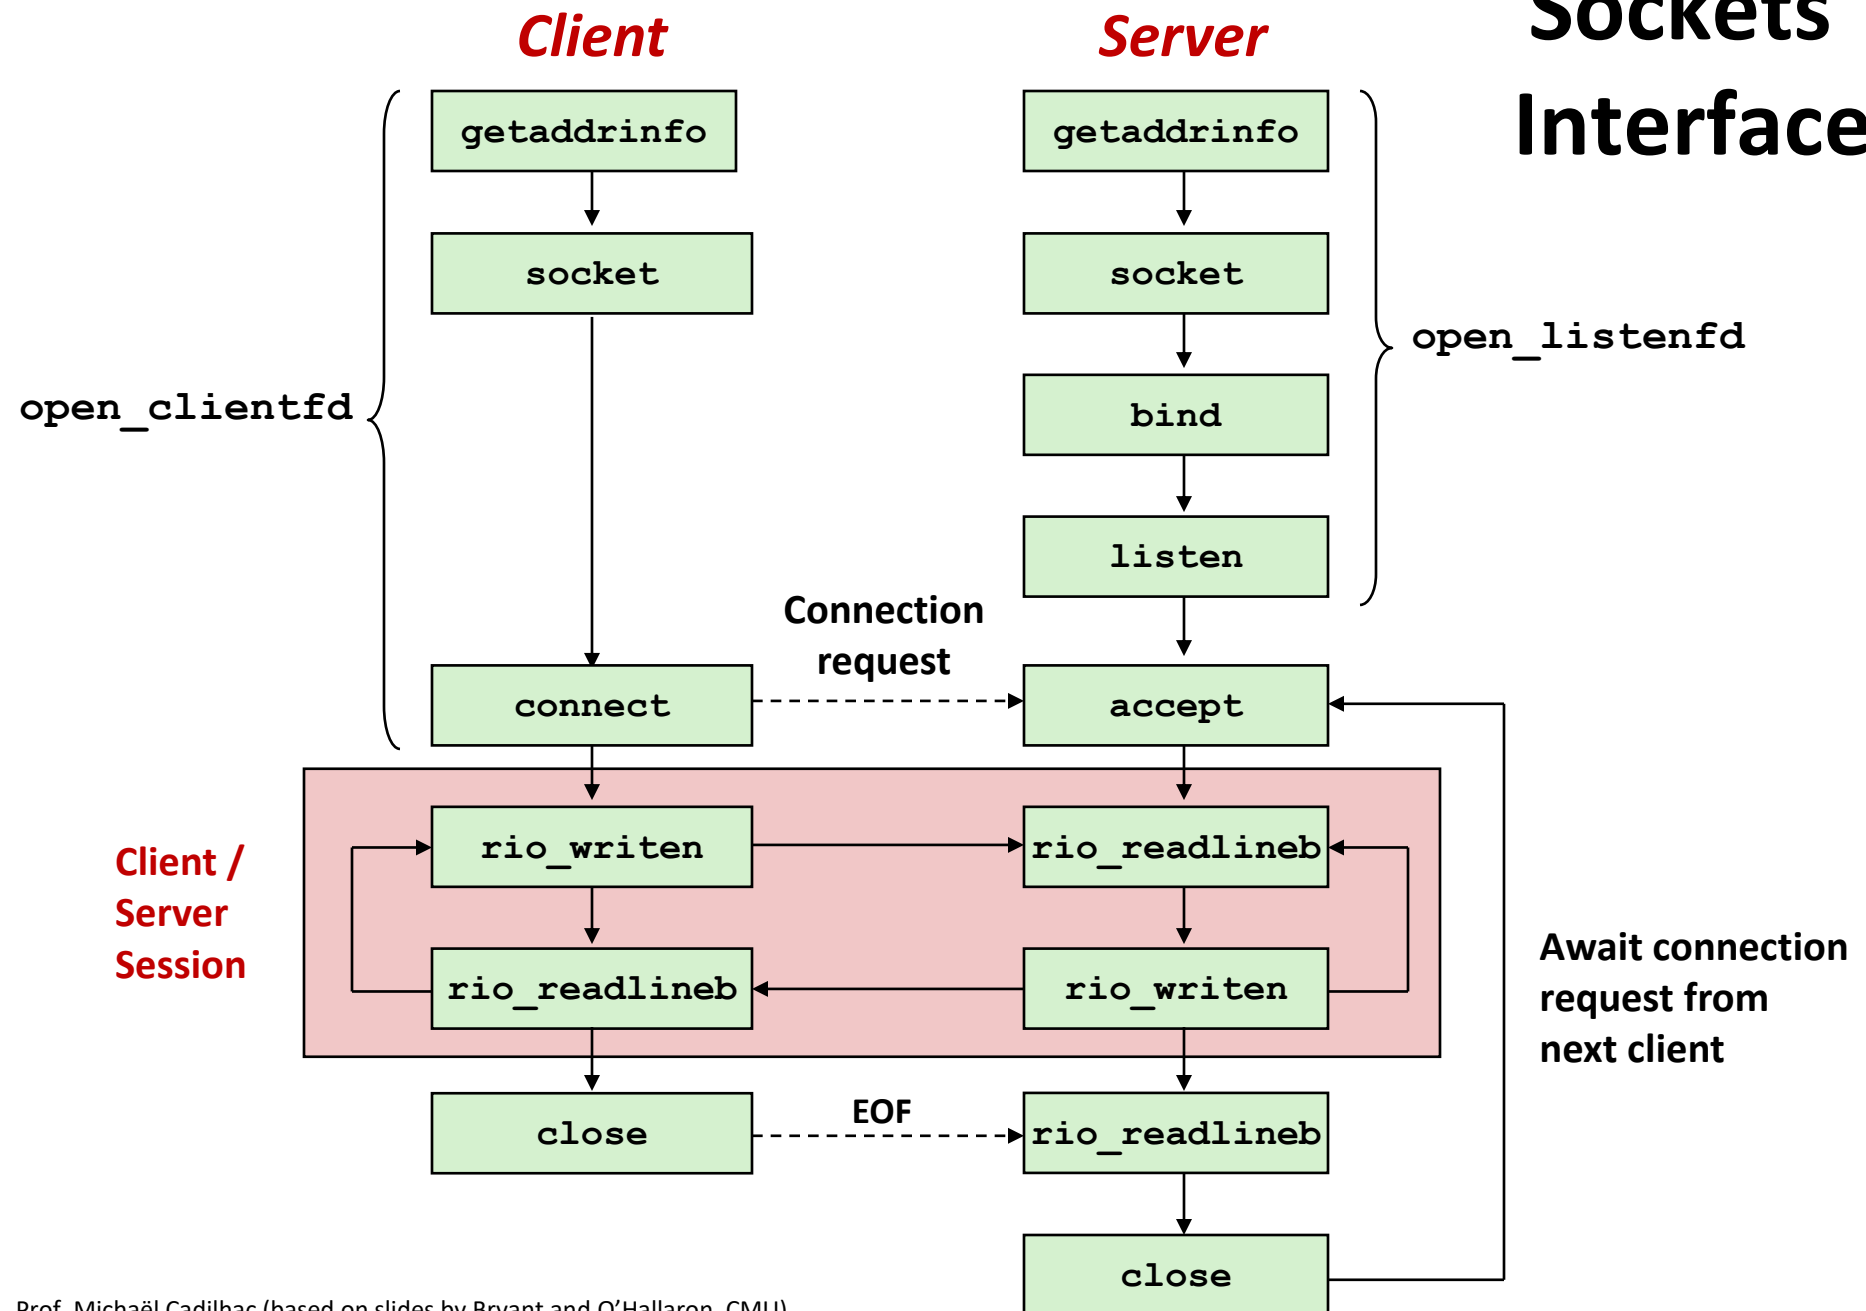

- Must cast (`struct sockaddr_in *`) to (`SA *`) for functions that take socket address arguments.

```
struct sockaddr_in {
    uint16_t      sin_family; /* Protocol family (always AF_INET) */
    uint16_t      sin_port;   /* Port num in network byte order */
    struct in_addr sin_addr;   /* IP addr in network byte order */
    unsigned char sin_zero[8]; /* Pad to sizeof(SA) */
};
```

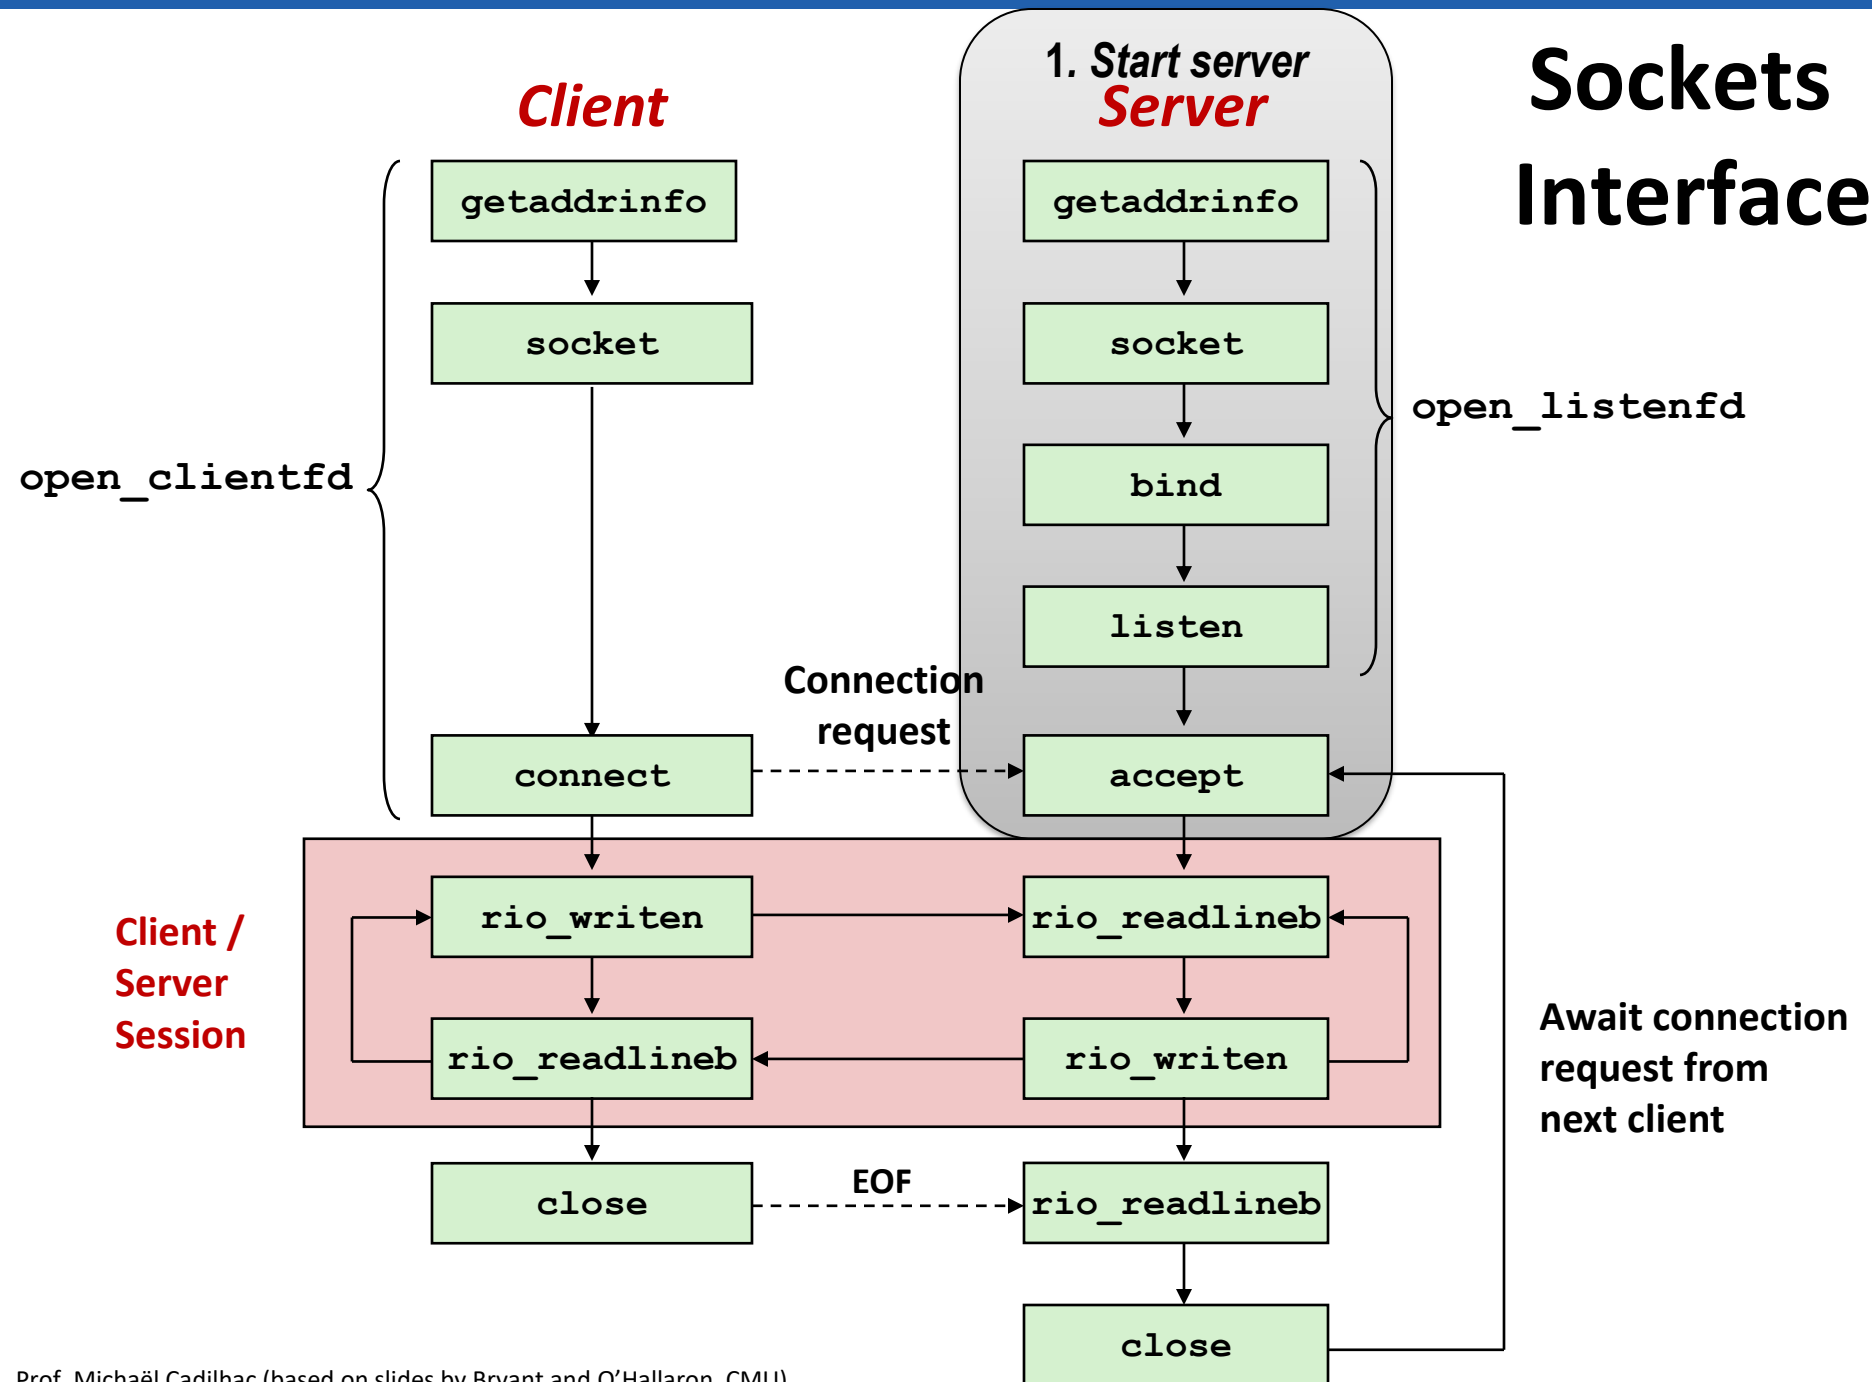

■ Usually, never filled by hand, but using `getaddrinfo`
